Algebra with SymPy

Ádám Gyenge

Outline

Linear Algebra

Solving Equations

Gröbner Bases

Rings, Ideals, and Modules

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

Number Theory

Defining Matrices in SymPy

- SymPy provides the Matrix class for defining and manipulating matrices.
- Entries can be numbers, symbols, expressions, etc.:

```
# Define symbols
a, b, c, d = sp.symbols('a b c d')
# Define symbolic matrices
M = sp.Matrix([[a, b]],
                  [c. d]])
N = sp.Matrix([[0, 1]])
                  [1, 0]])
 • Results in M = \begin{bmatrix} a & b \\ c & d \end{bmatrix} and N = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}.
```

Matrix Operations in SymPy

- SymPy supports the usual matrix operations.
- Examples:

```
# Transpose of a matrix
M.T
# Output: Matrix([[a, c], [b, d]])
# Scalar multiplication
2 * M
# Output: Matrix([[2*a, 2*b], [2*c, 2*d]])
# Element-wise addition
M + N
# Output: Matrix([[a, b + 1], [c + 1, d]])
```

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

Matrix Multiplication and Determinant

- Multiplication of matrices:
- M * N
- # Output: Matrix([[b, a], [d, c]])

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

Compute determinant:

M.det() # Output: a*d - b*c

Matrix Inversion and Eigenvalues

Compute inverse if the determinant is non-zero:

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

M.inv() # Output: Matrix([# [d/(a*d - b*c), -b/(a*d - b*c)], # [-c/(a*d - b*c), a/(a*d - b*c)]])

Eigenvalues and eigenvectors:

M.eigenvals() M.eigenvects()

Solving Equations with SymPy

- Use Eq for defining equations.
- Use solve() for solving algebraic equations.

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

For example, consider a quadratic equation

```
x = sp.symbols('x')
equation = sp.Eq(x**2 - 5*x + 6, 0)
solution = sp.solve(equation, x)
# Output: [2, 3]
```

Systems of Equations

We can also solve systems of linear equations:

```
x, y = sp.symbols('x y')
equations = (sp.Eq(2*x + y, 10), sp.Eq(3*x - y, 5))
solution = sp.solve(equations, (x, y))
# Output: {x: 3, y: 4}
```

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Nonlinear equations

SymPy can also be used to solve some nonlinear equations. For example, consider solving the following example:

Define a nonlinear equation: $x^3 - 6x^2 + 11x - 6 = 0$ equation = sp.Eq(x**3 - 6*x**2 + 11*x - 6, 0)

Solve the nonlinear equation
solution = sp.solve(equation, x)

Here the cubic equation $x^3 - 6x^2 + 11x - 6 = 0$ is solved, and the roots of the equation are x = 1, x = 2, and x = 3.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

>>> solution [1, 2, 3]

Trigonometric Equations

Here's an example of solving a simple trigonometric equation:

```
# Define the trigonometric equation: sin(x) = 0
equation = sp.Eq(sp.sin(x), 0)
```

Solve the trigonometric equation
solution = sp.solve(equation, x)

In this case, the equation sin(x) = 0 is solved, and the solutions are x = 0 and $x = \pi$.

Ideals

Let $(R, +, \cdot)$ be a (commutative) ring with 1.

Definition

A subset $I \subseteq R$ is an *ideal* if it is a subgroup for + and has the property $aI \subseteq I$ for all $a \in R$. That is, $x \in I$ and $a \in R$ implies $ax \in I$.

- The quotient group R/I inherits a uniquely defined multiplication from R which makes it into a ring.
- The mapping

$$\phi: R \to R/I, \quad a \mapsto a+I$$

is a surjective ring homomorphism

► Fact: There is a one-to-one order preserving correspondence between ideals J of R that contain I, and ideals J of R/I given by J = φ⁻¹(J).

Generators

Generating Set: An ideal I can be expressed as:

$$I = \langle f_1, f_2, \ldots, f_k \rangle = \left\{ \sum_{i=1}^k r_i f_i \mid r_i \in R \right\}.$$

Principal Ideal: If an ideal *I* has a single generator *f*, it is called a *principal ideal*:

$$I = \langle f \rangle = \{ r \cdot f \mid r \in R \}.$$

Example: In \mathbb{Z} , $4\mathbb{Z} = \{4k \mid k \in \mathbb{Z}\}$ is a principal ideal generated by 4.

Gröbner Bases

Let $R = k[x_1, x_2, ..., x_n]$ be a polynomial ring over a field k with n variables.

Definition (Buchberger, 1960s)

A Gröbner basis for an ideal $I \subseteq R$ is a finite generating set $G = \{g_1, g_2, \ldots, g_t\} \subseteq I$ such that the leading term of any polynomial in I (with respect to a chosen monomial order) is divisible by the leading term of some g_i in G. Formally, this means that for every $f \in I$, if LT(f) denotes the leading term of f, then there exists $g_i \in G$ such that $LT(g_i) \mid LT(f)$.

Gröbner Bases in Sympy

The groebner() method provides functions to compute Gröbner bases and perform related operations. Example:

Define variables
x, y, z = sp.symbols('x y z')

Define a system of polynomial equations
equations = [x**2 + y**2 - 1, x*y - z**2]

```
# Compute Groebner basis
gb = sp.groebner(equations)
```

The result is an object of type GroebnerBasis storing the elements of the basis of the ideal generated by the input polynomials as well as other data used or obtained during the computation:

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Monomial ordering

Definition

A monomial order is a total order on the set of all (monic) monomials in a given polynomial ring, satisfying the property of respecting multiplication: if $u \le v$ and w is any monomial, then $uw \le vw$.

Example

► Lexicographic Order (lex): Monomials are ordered lexicographically, e.g., x²y > xy² > y³.

Graded Reverse Lexicographic Order (grevlex): Monomials are ordered by total degree, with ties resolved using reverse lexicographic order.

In SymPy, use the argument order of groebner().

Monomial orders in SymPy

Applications of Gröbner Bases

Test if a polynomial belongs to an ideal:

```
f = 2*x**3 + y**3 + 3*y
result = gb.contains(f)
# Output: True
```

Test if an ideal is zero-dimensional:

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

gb.is_zero_dimensional
Output: True

Rings

In SymPy, the Domain class serves as the base class for constructing various types of rings. The following types of domains are available:

- 1. ZZ for integers
- 2. QQ for rational
- 3. GF(p) for finite fields of prime order.
- 4. RR for real (floating point) numbers.
- 5. CC for complex (floating point) numbers.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

- 6. QQ(a) for algebraic number fields.
- 7. K[x] for polynomial rings.
- 8. K(x) for rational function fields.
- 9. EX for arbitrary expressions.

Example of rings

For example, we can define the polynomials with integer coefficients, denoted $\mathbb{Z}[x]$, and the ring of polynomials with rational coefficients, denoted $\mathbb{Q}[x, y]$ as follows:

```
# Define variables
x, y = symbols('x y')
```

```
# Define rings
integer_poly_ring = sp.ZZ.old_poly_ring(x)
rational_poly_ring = sp.QQ.old_poly_ring(x, y)
```

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

This yields:

```
>>> integer_poly_ring
ZZ[x]
```

>>> rational_poly_ring
QQ[x,y]

Methods of Domain

- convert(element, target_domain): Converts an element to another domain.
- gcd(a, b): Computes the greatest common divisor of two elements.
- lcm(a, b): Computes the least common multiple of two elements.
- is_unit(element): Checks if an element is a unit (invertible).
- factor(element): Factors an element into irreducible components.
- add(a, b), mul(a, b), pow(a, n): Performs addition, multiplication, and exponentiation in the domain.
- zero, one: Returns the additive and multiplicative identities, respectively.

Structural properties

The Domain class also provides methods to determine the structural properties of algebraic domains, such as:

- The is_Field property checks if the domain is a field, meaning every non-zero element has a multiplicative inverse.
- The is_PID property verifies whether the domain is a PID, where every ideal is generated by a single element.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

```
>>> sp.QQ.is_Field
```

True

```
>>> sp.QQ.is_PID
True
```

```
>>> sp.ZZ.is_Field
False
```

```
>>> sp.ZZ.is_PID
True
```

We can construct an ideal in a ring using the ideal() method. As arguments, we need to specifying the generators of the ideal:

The above code creates the ideal $\langle y^2 - x^3 \rangle$ in the ring $\mathbb{Q}[x, y]$.

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

Operations on ideals

Sum of Ideals:

$$I+J=\{f+g\mid f\in I,g\in J\}.$$

The sum I + J is the smallest ideal containing both I and J. **Product of Ideals:**

$$I \cdot J = \left\{ \sum_{k=1}^m f_k g_k \mid f_k \in I, g_k \in J, m \in \mathbb{N} \right\}.$$

The product $I \cdot J$ consists of all finite sums of products of elements from I and J.

Intersection of Ideals:

$$I \cap J = \{f \in R \mid f \in I \text{ and } f \in J\}.$$

The intersection $I \cap J$ is the set of all elements common to both I and J.

Operations on ideals

SymPy also allows computation of common operations involving ideals:

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

```
>>> I_1=rational_poly_ring.ideal(y**2)
>>> I_2=rational_poly_ring.ideal(x**3)
```

```
# Sum of ideals
>>> I_1+I_2
<v**2,x**3>
```

Product of ideals
>>> I_1*I_2
<x**3*y**2>

Intersection of ideals
>>> I_1.intersect(I_2)
<x**3*y**2>

We can also form the quotient of a ring modulo an ideal. For this, we use the quotient() method or, simply, the sign /:

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

>>> rational_poly_ring/[x**2] QQ[x,y]/<x**2>

Modules

Let R be a ring (commutative, with unity 1_R).

Definition

An R-module is a set M equipped with two operations:

- Addition: + : M × M → M, such that M is an abelian group under +.
- Scalar multiplication: $\cdot : R \times M \rightarrow M$, satisfying:

Intuition: Modules generalize the concept of vector spaces, but over arbitrary rings instead of fields. **Examples:**

- $\triangleright \mathbb{Z}^n$ is a module over \mathbb{Z} .
- \triangleright R[x], the ring of polynomials over R, is a module over R.

Vector spaces are modules over fields.

Free modules

An module over a ring R is *free* if it is isomorphic to R^n for some n. In SymPy, we can work with free modules and modules constructed from them.

```
# Defining a free module
free_mod = rational_poly_ring.free_module(4)
# Defining a submodule
sub_mod = free_mod.submodule([1,x,y**2,x*y],[0,1,0,x**2])
The result is:
>>> free mod
QQ[x,y] **4
>>> sub_mod
<[1, x, y**2, x*y], [0, 1, 0, x**2]>
```

- ロ ト - 4 回 ト - 4 □

Integers and prime numbers

SymPy offers several utilities for analyzing and generating prime numbers, as well as factorizing integers into their prime components.

To check the primality of a number, factorize it, or generate primes within a range, we use the following:

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

```
# Check if a number is prime
>>> sp.isprime(17)
True
```

```
# Factorize an integer
>>> sp.factorint(60)
{2: 2, 3: 1, 5: 1}
```

Generate prime numbers within a range list(sp.primerange(10, 30)) [11, 13, 17, 19, 23, 29]

Divisors and modular arithmetic

```
# Find all divisors of an integer
>>> sp.divisors(28)
[1, 2, 4, 7, 14, 28]
```

```
# Compute modular inverse
>>> sp.mod_inverse(3, 7)
5
```

Here, divisors lists all divisors of a number, while mod_inverse computes the modular inverse when it exists. Modular inverses are particularly important in cryptography and solving congruences. The last result follows from $3 * 5 \equiv 1 \pmod{7}$.

Diophantine equations

Diophantine equations seek integer solutions to polynomial equations. SymPy's diophantine function can solve a variety of such equations, including linear, quadratic, and Pell's equations.

```
# Define variables
x, y, z = sp.symbols('x y z')
```

Result:

>>> solutions {(2*p*q, p**2 - q**2, p**2 + q**2)}

Chinese Remainder Theorem

Theorem: Let n_1, n_2, \ldots, n_k be pairwise coprime positive integers, and let $N = n_1 n_2 \cdots n_k$. Then for any integers a_1, a_2, \ldots, a_k , the system of congruences

 $x \equiv a_1 \pmod{n_1}$ $x \equiv a_2 \pmod{n_2}$ \vdots $x \equiv a_k \pmod{n_k}$

has a unique solution modulo N.

Example: Solve $x \equiv 2 \pmod{3}$, $x \equiv 1 \pmod{5}$, $x \equiv 3 \pmod{7}$.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ● ●

In SymPy, this is implemented through the crt function.

```
# Solve a system of modular congruences
moduli = [3, 5, 7]
remainders = [2, 1, 3]
solution = sp.crt(moduli, remainders) # (101, 105)
```

Here, the solution (101, 105) implies that $x \equiv 101 \mod 105$ satisfies the given congruences. The crt function handles both the solution and the modulus.
